## Hodges–Lehmann inequality and $\gamma$ -U-orderliness

- The Hodges-Lehmann estimator stands out as a unique robust location estimator due to its definition being substantially dissimilar from conventional L-estimators, R-estimators, and M-estimators. In their landmark paper, Estimates of location based on rank tests, Hodges and Lehmann (1) proposed two methods for computing the H-L estimator: the Wilcoxon score R-estimator and the median of pairwise means. The Wilcoxon score R-estimator is a location estimator based on signedrank test, or R-estimator, (1) and was later independently discovered by Sen (1963) (2, 3). However, the median of pairwise means is a generalized L-statistic and a trimmed U-statistic, as classified by Serfling in his novel conceptualized study in 1984 (4). Serfling further advanced the understanding by generalizing the H-L kernel as  $hl_k(x_1, ..., x_k) = \frac{1}{k} \sum_{i=1}^k x_i$ , where  $k \in \mathbb{N}$  (4). Here, the weighted H-L kernel is defined as  $whl_k(x_1, ..., x_k) = \frac{\sum_{i=1}^k x_i \mathbf{w}_i}{\sum_{i=1}^k \mathbf{w}_i}$ , where  $\mathbf{w}_i$ s are the weights applied to each element
  - applied to each element. By using the weighted H-L kernel and the L-estimator, it is now clear that the Hodges-Lehmann estimator is an LLstatistic, the definition of which is provided as follows:

$$LL_{k,\epsilon,\gamma,n} := L_{\epsilon_0,\gamma,n} \left( \operatorname{sort} \left( \left( whl_k \left( X_{N_1}, \cdots, X_{N_k} \right) \right)_{N=1}^{\binom{n}{k}} \right) \right),$$

- where  $L_{\epsilon_0,\gamma,n}(Y)$  represents the  $\epsilon,\gamma$ -L-estimator that uses the 19 sorted sequence, sort  $(whl_k(X_{N_1}, \dots, X_{N_k}))_{N=1}^{\binom{n}{k}}$ , as input, the upper asymptotic breakdown point of the L-estimator is  $\epsilon_0$ , 21 the lower asymptotic breakdown point is  $\gamma \epsilon_0$ .
