semiparametric | mean-median-mode inequality | asymptotic | unimodal | Hodges–Lehmann estimator

1. Hodges–Lehmann inequality and γ-U-orderliness

The Hodges–Lehmann estimator stands out as a unique robust location estimator due to its definition being substantially dissimilar from conventional L-estimators, R-estimators, and M-estimators. In their landmark paper, *Estimates of location based on rank tests*, Hodges and Lehmann [1] proposed two methods for computing the H-L estimator: the Wilcoxon score R-estimator and the median of pairwise means. The Wilcoxon score R-estimator is a location estimator based on signed-rank test, or R-estimator, [1] and was later independently discovered by Sen (1963) [2, 3]. However, the median of pairwise means is a generalized L-statistic and a trimmed U-statistic, as classified by Serfling in his novel conceptualized study in 1984 [4]. Serfling further advanced the understanding by generalizing the H-L kernel as $hl_k(x_1, \ldots, x_k) = \frac{1}{k}\sum_{i=1}^{k} x_i$, where $k \in \mathbb{N}$ [4]. Here, the weighted H-L kernel is defined as $whl_k(x_1, \ldots, x_k) = \frac{\sum_{i=1}^{k} x_i \mathbf{w}_i}{\sum_{i=1}^{k} \mathbf{w}_i}$, where $\mathbf{w}_i$s are the weights applied to each element.

By using the weighted H-L kernel and the L-estimator, it is now clear that the Hodges-Lehmann estimator is an LL-statistic, the definition of which is provided as follows:

$$LL_{k,\epsilon,\gamma,n} := L_{\epsilon_0,\gamma,n}\left(\text{sort}\left((whl_k(X_{N_1}, \cdots, X_{N_k}))_{N=1}^{\binom{n}{k}}\right)\right),$$

where $L_{\epsilon_0,\gamma,n}(Y)$ represents the ϵ_0,γ-L-estimator that uses the sorted sequence, $\text{sort}(whl_k(X_{N_1}, \cdots, X_{N_k}))_{N=1}^{\binom{n}{k}}$, as input, the upper asymptotic breakdown point of $L_{\epsilon_0,\gamma}$ is ϵ_0, the lower asymptotic breakdown point of $L_{\epsilon_0,\gamma}$ is $\gamma\epsilon_0$.
